

Credit ratings and the Euro Area sovereign debt crisis*

António Afonso^{§ #}, Davide Furceri^{⊕^N} and Pedro Gomes⁺

Abstract

We use EU sovereign bond yield and CDS spreads daily data to carry out an event study analysis on the reaction of government yield spreads before and after the announcements of the rating agencies (Standard & Poor's, Moody's and Fitch). We also perform causality tests between the effective rating and the sovereign spreads and test for contagion. Our results show: a significant response of government bond yield spreads to changes in both the rating notations and outlook, particularly in the case of negative announcements; announcements are not anticipated; bi-direction causality between ratings and spreads; evidence of spillover effects, specially from lower rated countries to higher rated countries.

JEL: C23; E44; G15.

Keywords: credit ratings; sovereign yields; rating agencies.

1. Introduction

After the 2008-2009 financial and economic crisis sovereign bond yield spreads increased markedly in several European Union (EU) countries, notably in the euro area, and mostly above what one would expect from the sum of inflation and real economic growth. The main cause of such developments has to be found in the increased awareness of capital markets towards the different macro and fiscal fundamentals of each country, notably the marked increase in fiscal imbalances in the aftermath of the crisis. Not surprisingly, several downgrades also occurred at the sovereign rating level, both impinging and reinforcing the upward movements in sovereign spreads.

Given that debt crises have been so far less of an issue for developed countries (Reinhart, 2010), previous work in the literature has focused on the relation between rating and yield and Credit Default Swap (CDS) spreads for emerging and developing economies. Moreover, we are not aware of any work analysing the response of yields (CDS) spreads to rating announcements for a large group of advanced economies.

This paper tries to fill this gap. We carry out an event study analysis to examine the effects of sovereign credit rating announcements of upgrades and downgrades (as well as changes in rating outlooks) on sovereign bond yield spreads in EU countries. We use daily data from January 1995 until October 2010, and also the spreads from the CDS.

Our contribution is twofold. First, we conduct an event study analysis looking at the reaction of yield spreads (and CDS spreads) two days before and after the announcements from the rating agencies: Standard & Poor's, Moody's and Fitch. A distinction between the three main rating agencies is done to assess whether some agencies have bigger or more lagged impacts on the sovereign bond markets. We also look whether spread developments anticipate, to some extent, rating movements.

Second, with the ratings converted into a numerical scale, we run a causality test between the transformed ratings and the yield (CDS) spreads. We also look at whether sovereign yields and CDS spreads in a given country react to rating announcements of other countries, and whether there are asymmetries in the transmission of these spillover effects.

According to our analysis, the main findings include: i) a significant response of government bond yield spreads to changes in both the rating notations and the rating outlook, particularly important for the case of negative announcements; ii) rating announcements are essentially not anticipated; iii) there is bi-direction causality between

ratings and spreads and iv) there is evidence of contagion, specially from lower rated countries to higher rated countries.

The remainder of the paper is organised as follows. Section two briefly reviews the related literature. Section three describes the data and some stylised facts. Section four conducts the empirical analysis and discusses the results. Section five concludes.

2. Related literature

The existing studies dealing with sovereign debt ratings, which are more related to our analysis, can be broadly grouped into two areas. First, we find papers that try to uncover the determinants of sovereign debt rating notations, notably via the estimation of both linear estimation methods and ordered response models (see, for instance, Afonso, 2003; Bissoondoyal-Bheenick, 2005 and Afonso, Gomes and Rother, 2010). These studies conclude that the rating scale is mainly explain by the level of GDP per capita, real GDP growth, external debt, the public debt level and the government budget balance.

Second, there are studies that address the explanatory power of sovereign ratings for the development of government bond spreads, which is closer to the event study analysis that we undertake here. For instance, Afonso and Strauch (2007) evaluate to which extent policy events taking place in the course of 2002, when the Stability and Growth Pact was put to a test, impinged of sovereign spreads. They find some mitigated effects of policy events on the euro interest rate swap spreads, the difference between the 10-year rate for the inter-bank swap market, and the 10-year government yield.

Kräussl (2005) conducts an event study analysis using daily sovereign ratings of long-term foreign currency debt from Standard & Poor's and Moody's. For the period under analysis, 1 January 1997 and 31 December 2000, they construct a so-called index of speculative market pressure to determine the ratings effect on financial markets. They report that sovereign rating changes and credit outlooks have a relevant effect on the size and volatility of lending in emerging markets, notably for the case of ratings' downgrades and negative outlooks.

Using also an event study for the period 1989–1997, with sovereign credit rating data from Standard & Poor's, Moody's, and Fitch, Reisen and von Maltzan (1999) find that a significant rating effect on the government bond yield spread when a country was put on review for a downgrade. They also report the existence of two-way causality between sovereign credit ratings and government bond yield spreads for the set of 29 emerging markets in their study.

Ismailescu and Hossein (2010) assess the effect of sovereign credit rating announcements on sovereign CDS spreads, and their possible spillover effects. According to their results, for daily observations from January 2, 2001 to April 22, 2009 for 22 emerging markets, positive events have a greater impact on CDS markets in the two-day period surrounding the event, being then more likely to spill over to other countries. Moreover, a positive credit rating event is more relevant for emerging markets. On the other hand, markets tend to anticipate negative events.

Finally, Gande and Parsley (2010) report that the existence of spillover effects across sovereign ratings, in a study for the period 1991-2000, for a set of 34 developed and developing economies. This implies that contagion effects are present when a rating event occurs and are, therefore, worthwhile being assessed as well.

3. Data and stylized facts

3.1. Sovereign ratings

The data for the credit rating developments are from the three main credit rating agencies: Standard and Poor's (S&P), Moody's (M) and Fitch (F). We transform the sovereign credit rating information into a discrete variable that codifies the decision of the rating agencies as depicted in Table 1. In practice, we use a linear scale to group the ratings in 17 categories, where the triple-A is attributed the level 17, and where we put together in the same bucket the few observations below B-, which all receive a level of one in the scale.¹

[Table 1]

On a given date the dummy variables upM and $downM$, as an example for Moody's, assume the following values:

$$upM_{it} = \begin{cases} 1, & \text{if an upgrade occurs} \\ 0, & \text{otherwise} \end{cases} \quad downM_{it} = \begin{cases} 1, & \text{if a downgrade occurs} \\ 0, & \text{otherwise} \end{cases} \quad (1.1)$$

A similar set of discrete variables were constructed for S&P and for Fitch. Alternatively to the credit rating announcements, we also consider the changes in the rating outlooks and we construct analogous discrete variables

¹ For instance, Reisen and Maltzan (1999) apply a logistic transformation and Afonso (2003) applies both a logistic and an exponential transformation, but Afonso, Gomes and Rother (2010) confirm that such transformations provide little improvement over the linear one.

$$posM_{it} = \begin{cases} 1, & \text{a positive outlook occurs} \\ 0, & \text{otherwise} \end{cases} \quad negM_{it} = \begin{cases} 1, & \text{a negative outlook occurs} \\ 0, & \text{otherwise} \end{cases} \quad (1.2)$$

Given that changes in the outlook tend to anticipate movements in the rating notation, the information content of the outlook is in itself valuable for explaining the movements of the yield spreads.

3.2. Data set

In the analysis we cover twenty four EU countries: Austria, Belgium, Bulgaria, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, and United Kingdom. No data were available for Cyprus, Estonia and Luxembourg.

The daily dataset starts as early as 2 January 1995 for some countries and ends on 10 October 2010. The data for the sovereign rating announcements and rating outlook changes were provided by the three rating agencies: Standard and Poor's, Moody's and Fitch. It covers between 96000 and 99000 observations.

The data for the sovereign bond yields, which is for the 10-year government bond, end-of-day data, comes from Reuters (68376 observations). The data for the CDS spreads is for 5-year senior debt, and comes from DataStream (historical close - Euro). Regarding the CDS spreads daily dataset, in some cases it starts as early as 1 January 2003, implying the availability of a maximum of 36713 observations in that case. Additionally, we also use an equity index, as reported in Datastream, which starts as early as of 1 January 2002 (57272 observations).²

3.3. Stylised facts

In total, since 1995, there were 394 rating announcements from the three agencies. S&P and Fitch were the most active agencies with 150 and 138 announcements, whereas Moody's only had 108. Out of these announcements, mostly of them were upgrades (167) and positive outlook announcements (88) rather than downgrades and negative outlooks (79 and 60, respectively).³

² The respective country indices are described in the Data Annex.

³ A full summary of rating announcements is provided in the Appendix. We also report, per country, the data for the sovereign yield, CDS spreads and rating developments.

However, and because we only have data on sovereign yields and CDS spreads starting at a later period, we can not use the full set of rating announcements. Therefore, in our study we have 191 announcements overlapping with sovereign yield data, 167 overlapping with CDS spreads data and 252 overlapping with stock market returns.

The sovereign yield data are not fully available or are less reliable for several eastern European countries, namely Romania, Lithuania, Latvia, Estonia or Slovenia. On the other hand, with CDS data there is a lower weight of rating announcements in the Euro Area and a bigger weight of the other EU27 countries.

Table 2 shows the average sovereign yield spread over Germany and the average CDS spread for the different rating notations. We can see that, on average, AAA countries have a spread of 0.2 percentage points over German 10 year bonds. As the rating deteriorates, the spread goes up. The rated countries rated AA- and A+ pay 1 percentage point more than Germany to issue sovereign debt. For the A- rating the spread is around 2 percentage points. Closer to “junk” grade, spreads are between 3 and 5 percentage points.

[Table 2]

Figures 1 and 2 depict respectively the sovereign yield spread and the CDS spread, 10 days before and up to 10 days after the rating announcements. This simple illustrative exercise shows that sovereign yields tend to accompany more downgrade announcements, and the magnitude of the changes in the spreads is also higher in those cases. Regarding CDS spreads, there seems to be some downward movement before rating upgrades, while in the case of outlook announcements this is less anticipated.

[Figure 1]

[Figure 2]

4. Empirical analysis

This section assesses the relation between rating announcements and sovereign yield and CDS spreads along three main dimensions:

i) analyzes the reaction of rating announcements on yields and CDS spreads, and looks notably at whether: a) the effect is anticipated, b) the effect is different between the Economic and Monetary Union (EMU) and non-EMU countries, c) the reaction of yields and CDS markets has increased after the onset of the 2008 financial crisis;

ii) assesses whether sovereign ratings lead or cause changes in the yields and CDS spreads beyond and above other observable yields determinants;

iii) gauges whether sovereign yields and CDS spreads in a given country react to rating announcements of other countries, and whether there are asymmetries in the transmission of these spillover effects.

4.2. Event study

To analyze how sovereign yields (and CDS) spreads respond to sovereign credit ratings and to credit outlook announcements we apply a standard event study methodology. In particular, we measure the response of the yield and CDS spreads over a two-day period $(-1, 1)$, where the rating event is considered to occur at time zero. The use of a narrow window of two days, compared to, say, ten or thirty days, allows reducing contamination problems which may bias the results of the analysis.

The standard event study approach usually links rating events to abnormal movements in the spread index (ΔS), which is given by the difference between model generated (\bar{S}) and actual movements (S):

$$\Delta S_{it} = \bar{S}_{it} - S_{it}, \quad (2)$$

where the model-generated movements are defined as

$$\bar{S}_{it} = \alpha_i + \beta_i S_{it} + \varepsilon_{it}, \quad (3)$$

with $E[\varepsilon_{it}] = 0$, $\text{Var}[\varepsilon_{it}] = \sigma_i^2$.

The coefficients for the model-generated movements, when enough observations are available, should be computed for the periods where no rating event takes place. Otherwise, and as suggested by Campbell et al. (1997), one may need to constrain α_i and β_i to be zero and one, respectively. This implies that we have to base the event study on the observed bonds yields (and CDS) spread between sovereign entities and German bonds. In addition, and to control for changes in EU market conditions we compute an adjusted measure of sovereign yields (and CDS) spreads as the difference between the sovereign's yield (and CDS) spread and the spread of an equally weighted portfolio created of all the EU countries in the sample.

Table 3 reports the average change between $t+1$ and $t-1$ in the adjusted measure of sovereign yields (in decimal points) spreads and CDS (in basis points) spreads during the occurrence of a rating event at time t . A positive (negative) rating event for a given agency takes place when there is an upgrade (downgrade) of the credit rating or an upward (downward) revision in the sovereign's credit outlook. The results in the table show that

while there is a significant reaction of sovereign yield spreads and particularly CDS spreads to negative events, the reaction to positive events is much more muted. This result is consistent with previous studies in the literature which generally conclude that only negative credit rating announcements have significant impacts on yields and CDS spreads (Reisen and von Maltzan, 1999; Norden and Weber, 2004; Hull et al. 2004; Kraussl, 2005).

[Table 3]

Considering all announcements among the different rating agencies, the results suggest that while a negative event increases the yields (CDS) sovereign spreads by 0.08 (0.13 percentage points), a positive event reduces the CDS sovereign spreads by around 0.01 percentage points. Analyzing the market's reaction to announcements of different agencies, the results in the table suggest that while sovereign yields spreads react significantly only to negative S&P's announcements (and marginally to positive announcements from Moody's), sovereign CDS spreads increase in the presence of negative Moody's and Fitch's announcements, and decrease when positive S&P announcements occur. Finally, while the reaction in the yields sovereign spreads seems to take place mostly during the second day of the two-day period, the reaction in the CDS spreads mostly occurs during the first day.

We repeat the event study analysis by disaggregating negative (positive) events between periods of rating downgrades (upgrades) and periods of negative (positive) outlook revisions. The results reported in Table 4 suggest that for negative events both sovereign yields and CDS spreads respond very similarly to rating downgrades and negative outlook revisions. In contrast, among positive rating events, the results suggest that sovereign CDS spreads are more responsive to positive outlook revisions than the yield spreads.

[Table 4]

Successively, we have tested whether the effect of rating announcements on sovereign yields and CDS spreads is different between EMU and non-EMU countries.⁴ To this purpose we repeated the event study analysis for both EMU and non-EMU countries, recalculating for each group the adjusted measure of sovereign yield and CDS spreads by using the equally weighted portfolio yield spreads and CDS spreads in each of the two samples.

⁴ In our sample we have 14 EMU countries: Austria, Belgium, Finland, France, Germany, Greece, Ireland, Italy, Malta, Netherlands, Portugal, Slovakia, Slovenia, and Spain, being 10 the number of non-EMU countries.

The results for the overall sample and the two country groups are reported in Table 5. When looking at the table, we can conclude that the response of both sovereign yields and CDS spreads is qualitatively similar between EMU and non-EMU countries. In particular, and considering all rating announcements from the three rating agencies, while a negative event increases yields (CDS) spreads by 0.9 (0.11) percent in EMU countries, the increase in yields (CDS) spreads in non-EMU countries is about 0.8 (0.13) percent. Sovereign yields respond weakly (and negatively) to positive events in EMU countries but not in non-EMU countries. Overall, the difference in the results is never statistically significant. For the case of the non-EMU countries, when positive rating events take place, the CDS spreads only react to negative S&P announcements.

[Table 5]

The results presented so far, drawing on a standard event study analysis, may suffer from a specification problem and therefore be biased. Indeed, the event study approach, based on the test of the means fails to account for the pattern of bond yields (CDS) spreads that might bias the estimated reaction of bond yields (CDS) spreads to current rating changes. To correct for this problem, we assess how sovereign yields (and CDS) spreads respond to sovereign credit ratings and to credit outlook announcements by estimating a country fixed effect panel regression of (adjusted measures) of sovereign yields (and CDS) spreads on rating dummies (D):

$$S_{it} = \alpha_i + \rho S_{it-1} + \beta D_{it} + \varepsilon_{it}, \quad (4)$$

where S refers to the adjusted measures of sovereign yields (and CDS), α_i are country fixed effects and D is a dummy that takes value equal to 1 when the credit rating (or outlook) changes (as explained in (1.1) and (1.2)).

The estimations results reported in Table 6 are qualitatively similar to those reported in Table 4, and confirm the finding that mostly negative credit rating announcements have significant positive impacts on yields and CDS spreads. For instance, considering all announcements from the different rating agencies, the results show that a negative rating event increases the yields (CDS) sovereign spreads by 0.08 (0.05 percentage points). On the other hand, positive rating announcements of S&P and Moody's reduce CDS spreads.

[Table 6]

Finally, we test whether the effect of rating announcements has changed over time. In this case, we are interested in analyzing whether the reaction of sovereign markets to rating announcements has become stronger during the recent period of financial turbulence. To this purpose, we re-estimate equation (4) after and before the 15th of September of 2008

(the day in which Lehman Brothers filed for bankruptcy protection). The results reported in Table 7 suggest that while the reaction of sovereign yields spread has remained broadly unchanged, the reaction of CDS spreads to negative rating events has increased considerably after the beginning of the crisis.

[Table 7]

The difference in reaction between sovereign yields and CDS to rating announcements is consistent with the fact that financial sovereign markets have become particularly exposed to “bad” news and that CDS have significantly increased more than yields after the collapse of Lehman Brothers. Indeed, while average sovereign yields spreads have increased by 81 basis points (from 66 to 147 basis points), average sovereign CDS spreads have raised by 127 basis points (from 18 to 145 basis points).

4.3. Testing anticipation

The results presented so far have shown that both sovereign yields and CDS spreads mostly react to (negative) rating announcements. The question that arises is whether both sovereign yields and CDS have already absorbed the information contained in changes in the ratings before their announcements. To test for this hypothesis we re-estimate equation (3) considering the adjusted measure of sovereign yields (and CDS) spreads over two different 30 and 60 days windows: [-30,-1] and [-60,-1]. To avoid contamination, rating events that were preceded by other events in the same country in the previous 30 days (for the period [-30,-1]), or 60 days (for the period [-60,-1]) are eliminated.

Table 8 reports the estimates relative to S&P announcements (the results are qualitatively unchanged when Moody’s and Fitch’s announcements are analyzed).⁵ Looking at the table, it is evident that information contained in both downward and upward outlook revisions is not anticipated by sovereign yield and CDS markets. In contrast, while sovereign yield markets do not anticipate rating announcements, there is (weak) evidence that CDS markets seems to anticipate the information contained in rating downgrades. Such mostly lack of anticipation may also imply that in some cases rating events go for some reason astray of the underlying macro and fiscal fundamentals perceived by markets’ participants (on this issue see also Afonso and Gomes, 2010).

[Table 8]

The absence of any statistical significance regarding the anticipation effects of positive announcements can be explained by two factors. First, our previous analysis has found

⁵ The results are available from the authors upon request.

strong empirical evidence that both sovereign yields and CDS spreads react mostly to negative announcements. Second, while there is a high incentive for governments to leak good news to rating agencies (Gande and Parsley, 2005), this incentive is null in the case of bad news.

4.4. Causality

For the purpose of exploring the nexus of causality between rating changes and yield (or CDS) spreads we employ Granger causality tests in a panel framework. Therefore, in order to have a meaningful number of (non-zero) observations for changes in ratings we construct a measure of average rating across agencies (R) as:

$$R_{it} = (1/3)[(SP_{it} + F_{it} + M_{it}) + 0.5(posSP_{it} + posF_{it} + posM_{it}) - 0.5(negSP_{it} + negF_{it} + negM_{it})] \quad (5)$$

where and the variables SP , F , and M , take the values between 1 and 17 as explained in Table 1.

Causality tests can then be performed by estimating separate regressions of the changes of spreads and ratings:

$$\Delta S_{it} = \sum_{i=1}^k \gamma_0^i \Delta S_{it-i} + \sum_{i=1}^k \gamma_1^i \Delta R_{it-i} + \sum_{i=1}^k \gamma_2^i \Delta Z_{it-i} + \varepsilon_{it} \quad (6)$$

$$\Delta R_{it} = \sum_{i=1}^k \lambda_0^i \Delta S_{it-i} + \sum_{i=1}^k \lambda_1^i \Delta R_{it-i} + \sum_{i=1}^k \lambda_2^i \Delta Z_{it-i} + \omega_{it} \quad (7)$$

$$\Delta Z_{it} = \sum_{i=1}^k \delta_0^i \Delta S_{it-i} + \sum_{i=1}^k \delta_1^i \Delta R_{it-i} + \sum_{i=1}^k \delta_2^i \Delta Z_{it-i} + \mu_{it} \quad (8)$$

where Z is a vector of variables influencing sovereign yields (and CDS) spreads and the credit rating. Ideally, the vector Z should include all the determinants of sovereign yields and CDS spreads and rating changes. Previous results in the literature (for instance, Afonso et al. 2010) suggest considering as these determinants macroeconomic variables such as: GDP per capita, GDP growth, domestic and foreign debt, public deficit, and financial variables. However, given that daily observations are only available for high frequency financial variables we restrict our vector Z to stock market returns (daily log returns of the equity indexes).

Hence, we test if ratings cause the spreads, by regressing the change in spreads, on its own lags and lags of the change in rating, and test the joint significance of all coefficients

of ratings. Although we include lags of the dependent variable, we estimate each equation with country fixed effects. First, we have a very large number of time observations, so the bias should be close to zero. Furthermore, estimating the equation with GMM would imply that taking the differences of the differences of the variables, which would amplify the noise in the regression. To test the joint significance of the coefficients, we use the likelihood ratio test.

[Table 9]

As in Reisen and von Maltzan (1999), we find two-way causality between sovereign credit ratings and government bond yield spreads (Table 9). Past values of changes in yield (CDS) spreads are significant determinants of the change in effective rating and vice-versa. We also reject the null that the stock market does not cause both the yield (CDS) spreads and the rating. On the other hand, in one set of regressions, we could not reject the null that the yield spreads and the rating do not cause the stock market returns. However, when we use the CDS spread, we do reject the null. Our estimates indicate that, while deriving information already available on the market, the ratings influence spreads beyond those fundamentals.

4.5. Contagion

The results of the previous section have provided strong empirical evidence that both sovereign yields and CDS spreads in a given country react to rating announcements concerning that country, and also that bivariate causality exists. Another question that arises is whether sovereign yields spreads and CDS spreads in a given country also react to rating announcements for the other countries. In other words, we want to answer the question of whether spillover effects exist.

To test for this hypothesis we regress the change of sovereign yields (CDS) spreads⁶ of a non-event country ($\Delta S_{it}^{non-event}$) on the average change in the rating in event countries:

$$\Delta S_{it}^{non-event} = \alpha_i + \beta \overline{\Delta R_{it}^{event}} + \varepsilon_{it}, \quad (9)$$

where R is the average rating across agencies defined in the Granger causality section (equation (5)) and $\overline{\Delta R}$ is the average change of R across event countries.

⁶ The analysis of the spillover effect is carried out using the sovereign yields (CDS) spreads change instead of the adjusted measure. The reason to do so is that the use of the adjusted measure will tend to understate spillover effects (Jorion and Zhand, 2007; Ismilesu and Kazemi, 2010).

In addition we test whether spillover effects depend on the difference in credit rating qualities between event and non-event countries ($R_{it}^{non-event} - \overline{R_{it}^{event}}$):

$$\Delta S_{it}^{non-event} = \alpha_i + \beta \overline{\Delta R_{it}^{event}} + \delta (R_{it}^{non-event} - \overline{R_{it}^{event}}) + \gamma \overline{\Delta R_{it}^{event}} (R_{it}^{non-event} - \overline{R_{it}^{event}}) + \varepsilon_{it}. \quad (10)$$

Alternatively, we estimate equations (10) and (11) with: i) country fixed-effects; ii) country fixed effects and a time trend; iii) country fixed effects and time fixed effects. The results reported in Table 10 provide evidence of significant spillover effects for sovereign yields markets. In particular, looking at the results of the first column of each empirical approach, it is possible to observe that one (unconditional) increase in the average rating, R , in country-events decreases sovereign yields by 0.1 percent in non-event countries. In contrast, spillover effects are mostly not significant for sovereign CDS spreads. A possible explanation for this different result between CDS and yields spread is that while local investors have long enjoyed participation in sovereign debt market, they have had relatively limited participation in sovereign CDS markets, which makes them less informative and reactive (Ranciere, 2002; Isamilescu and Kazemi, 2010).

[Table 10]

Our results also show that the spillover effects for the yield spreads are asymmetric and are a function of the difference in credit rating qualities. For instance, we find that rating announcements in event countries affect more significantly sovereign yields in non-event countries when the rating of the event country is lower than those of non-event countries. In other words, non-event countries with a better credit rating will experience a significantly larger change in its sovereign yields spreads than a lower credit quality rating. This result is consistent with previous finding in the literature (Gande and Parsley, 2005; Isamilescu and Kazemi, 2010).

Overall, our results suggest that given that differences in rating reflect, among other factors, differences in fiscal positions, the results can be also interpreted as evidence of some spillover effects from countries with weaker fiscal positions to countries with stronger fiscal positions.

5. Conclusion

In this paper we have assessed to what extent sovereign credit rating announcements impinge on the behaviour of sovereign yield spreads and CDS for the EU countries. Therefore, we have carried out an event study analysis for a panel of EU sovereign bond

yields and CDS spreads with daily data from January 1995 until October 2010. The so-called events are the sovereign credit rating announcements and the changes in the credit rating outlook from the three major rating agencies (Standard & Poor's, Moody's and Fitch).

Our main results can be summarised as follows: i) we find a significant response of government rating bond yield spreads to changes in both the credit rating notations and in the outlook (with some differences across rating agency); ii) the response results are particularly important for the case of negative announcements, while the reaction of spreads to positive rating events is more mitigated; iii) sovereign yield spreads respond negatively (and weakly) to positive events in the EMU countries, but not in the non-EMU country sub-sample, while the response to negative events in this case is quantitatively similar across country-sub-sample; iv) the reaction of CDS spreads to negative rating events has increased after the 15th of September 2008 Lehman Brothers bankruptcy; v) rating and outlook announcements are essentially not anticipated since we find only weak evidence that CDS markets anticipate rating downgrades; vi) there is evidence of bi-direction causality between sovereign ratings and spreads; vii) in addition, we also reject the hypothesis that stock market returns do not cause the yield spreads, but we cannot reject the hypothesis that yield spreads and ratings do not cause stock market returns; viii) finally, we find evidence of rating announcement spillover effects, particularly from lower rated countries to higher rated countries.

The abovementioned conclusions shed some additional light on the behaviour of capital markets vis-à-vis sovereign credit rating developments. The fact that negative rating events take markets mostly by surprise, can either imply that fundamentals are not fully discounted on a more permanent basis by markets participants or that rating events have, to some extent, gone astray of such underpinnings in some events. On the other hand, our analysis also shows that the reaction of euro area spreads to credit rating events is clear and quick (within one to two days), which implies that good macroeconomic fundamentals and sound fiscal positions are key to prevent, first, rating downgrades, and then, the upward movement in yields and spreads.

Figure 1 – Yield spreads before and after an announcement

Note: based on 73 upgrades, 31 downgrades, 37 positive outlook and 28 negative outlook announcements for the 3 agencies. The number of days is in the horizontal axis.

Figure 2 – CDS spreads before and after an announcement

Note: based on 36 upgrades, 63 downgrades, 23 positive outlook and 44 negative outlook announcements for the 3 agencies. The number of days is in the horizontal axis.

Table 1 – S&P, Moody's and Fitch rating systems

Characterization of debt and issuer (source: Moody's)	Rating			Linear transformation
	S&P	Moody's	Fitch	
Highest quality	AAA	Aaa	AAA	17
High quality	AA+	Aa1	AA+	16
	AA	Aa2	AA	15
	AA-	Aa3	AA-	14
Strong payment capacity	A+	A1	A+	13
	A	A2	A	12
	A-	A3	A-	11
Adequate payment capacity	BBB+	Baa1	BBB+	10
	BBB	Baa2	BBB	9
	BBB-	Baa3	BBB-	8
Likely to fulfil obligations, ongoing uncertainty	BB+	Ba1	BB+	7
	BB	Ba2	BB	6
	BB-	Ba3	BB-	5
High credit risk	B+	B1	B+	4
	B	B2	B	3
	B-	B3	B-	2
Very high credit risk	CCC+	Caa1	CCC+	
	CCC	Caa2	CCC	
	CCC-	Caa3	CCC-	
Near default with possibility of recovery	CC	Ca	CC	
			C	1
Default	SD	C	DDD	
	D		DD	
			D	

Table 2 – Average sovereign yield and CDS spreads

Rating	Average yield spread over Germany (%)			Average CDS spread over Germany (bp)		
	S&P	Moody's	Fitch	S&P	Moody's	Fitch
AAA	0.18	0.21	0.19	11.1	15.0	12.9
AA+	0.34	0.42	0.51	25.0	30.5	45.2
AA	0.58	0.57	0.31	49.2	35.3	17.3
AA-	1.09	0.63	1.09	17.7	9.5	72.1
A+	0.95	1.35	1.05	49.9	38.3	53.6
A	0.83	1.92	0.76	55.3	84.1	33.1
A-	1.76	2.10	2.15	60.8	149.5	69.8
BBB+	2.75	3.70	2.71	96.8	302.8	102.5
BBB	4.06	5.84	3.14	246.8	-	164.7
BBB-	5.05	2.39	4.59	144.7	225.6	248.1
<BB+	3.79	3.63	2.49	371.7	107.0	373.5

Note: Yields spreads are expressed in decimal points; CDS in basis points. Mean with associated t-statistics reported in brackets.

(β) Rating differences	-	-0.013 (0.02)	-	-0.007 (-0.22)	-	-0.048 (-0.83)
(γ) Interaction	-	-0.088 (-1.58)	-	-0.086 (-1.58)	-	-0.072 (-1.52)

Note: Yields spreads are expressed in decimal points; CDS in basis points. Mean with associated t-statistics reported in brackets. T-statistics reported in the table. ***, **, * means significance at 1%, 5%, 10% respectively. FE – fixed effects.

Data annex

Daily sovereign yield data come from Reuters. The respective tickers are: BE10YT_RR, DE10YT_RR, IE10YT_RR, GR10YT_RR, ES10YT_RR, FR10YT_RR, IT10YT_RR, NL10YT_RR, AT10YT_RR, PT10YT_RR, FI10YT_RR, MT10YT_RR, SI10YT_RR, SK10YT_RR, DK10YT_RR, GB10YT_RR, BG10YT_RR, CZ10YT_RR, HU10YT_RR, LT10YT_RR, LV10YT_RR, PL10YT_RR, RO10YT_RR, SE10YT_RR.

Daily 5-year Credit default swaps spreads, historical close, are provided by DataStream.

Daily equity indexes are provided by Datastream:

Germany - Equity/index - DAX 30 Performance Index - Historical close - Euro

France - Equity/index - France CAC 40 Index - Historical close - Euro

Athens Stock Exchange ATHEX Composite Index - Historical close - Euro

Standard & Poors/MIB Index - historic close - Euro

Portugal PSI-20 Index - historic close - Euro

Amsterdam Exchange (AEX) Index - historic close - Euro

Spain IBEX 35 Index - historic close - Euro

Belgium BEL 20 Index - historic close - Euro

Ireland Stock Exchange Overall (ISEQ) Index - historic close - Euro

Nordic Exchange OMX Helsinki (OMXH) Index - historic close - Euro

Austrian Traded Index (ATX) - Percentage change in the latest trade price or value from the historic close - Euro

Slovenian Stock Exchange (SBI) Index - Percentage change in the latest trade price or value from the historic close - Euro

Cyprus Stock Exchange General Index - Historical close - Euro

Malta Stock Exchange Index - Percentage change in the latest trade price or value from the historic close - Maltese lira

Slovakia SAX 16 Index - Percentage change in the latest trade price or value from the historic close - Euro

Bulgaria Stock Exchange SOFIX Index - Historical close, end of period - Bulgarian lev, provided by Bloomberg

Prague PX 50 Index - Historical close, end of period - Czech koruna

Nordic Exchange OMX Copenhagen (OMXC) 20 Index - Historical close, end of period - Danish krone

Nordic Exchange OMX Tallinn (OMXT) Index - Historical close, end of period - Estonian kroon

Nordic Exchange OMX Riga (OMXR) Index - Historical close, end of period - Latvian lats

Nordic Exchange OMX Vilnius (OMXV) Index - Historical close, end of period - Lithuanian litas

Budapest Stock Exchange BUX Index - Historical close, end of period - Hungarian forint

Warsaw Stock Exchange General Index - Historical close, end of period - Polish zloty

Romania BET Composite Index (Local Currency) - Historical close, end of period - Romanian leu

Nordic Exchange OMX Stockholm 30 (OMXS30) Index - Historical close, end of period - Swedish krona

Financial Times Stock Exchange (FTSE) 100 Index - Historical close, end of period - UK pound sterling
