Abstract

Besides being an innovation in itself, Bitcoin has resulted in the creation of well over 100 exchanges on which Bitcoins can be traded for various currencies. These exchanges often make it possible to exchange bitcoins for multiple currencies, which makes it possible for exchange participants to exchange currencies. This is difficult to do elsewhere. Trading on these exchanges is not limited to parties such as brokers or dealers, with anyone allowed to participate after the identity checks necessary in some countries. Trading is open 24/7 every day of the year. One purpose of this paper is to examine this innovative market structure compared to the use of brokers and dealers. We also will examine the markets' efficiency at reflecting information and at executing trades.

Bitcoin exchanges also are different from typical exchanges such as stock exchanges because they are not regulated in the same way that stock exchanges are regulated. The regulations that apply have more in common with eBay than with stock exchanges. Nonetheless, Bitcoin exchanges are asset exchanges. One purpose of this paper is examine the costs and benefits of this unregulated structure.

We have downloaded data on all trades including price and volume information for all exchanges available at <http://api.bitcoincharts.com/v1/csv/>. A basic summary of these data is presented in Table 1 for the 223 exchanges available there. We will update these data after 1/1/2018. These data go through January 12, 2017. We are supplementing this with additional information. Some exchanges stopped reporting prices and trades to this source but continued in operation and we are organizing that information. In addition, there is some information available for some other exchanges and we are collecting that.

Second, these “exchanges” include LocalBitcoins, which are more similar to Craigslist than an exchange. The exchanges operate as one might expect. A person who wants to trade on an exchange transfers currency (possibly including cryptocurrency) to the exchange’s accounts. Then the trader can buy and sell based on the value of various assets at the exchange. These exchanges are initiated over the

Internet and require no physical presence in any particular location to trade. There is little short selling possible on these exchanges.

On LocalBitcoins, buyers and sellers advertise bid and ask prices at various locations around the world. Often a person will be both a buyer and a seller, and we call these people “traders.” A purchase from a trader can be executed in person or can be executed by a deposit into a bank account controlled by the trades which is followed by the trader transferring cryptocurrency to the buyer. Sales generally are in person because execution without personal contact would require the seller to transfer the cryptocurrency to the trader and then provide bank information to make a transfer of funds to the seller. This would require an extraordinary level of trust in a stranger.

Table 1 shows the volume and number of trades on the exchanges and the dates for which we have data on prices. Bid-ask spreads differ across exchanges and especially between LocalBitcoins and the exchanges. We will summarize these data. Furthermore, prices differ across exchanges and we will examine the relationship between these prices. While there are reports of arbitrage by some agents, especially given the level of prices now over \$10,000, the prevalence and importance of it is not apparent.

Table 2 shows the currencies and cryptocurrencies traded on each of the exchanges plus LocalBitcoins and the number of exchanges that traded a currency for some period. (We apologize for only having ISO codes in the table but we are in the process of organizing the data.)

We are putting together graphs for the exchanges which will show the development of the exchanges.

A natural question is the informational efficiency of these exchanges. We did some preliminary calculations using an index of daily prices from the online publication CoinDesk (<https://www.coindesk.com/api/>) and found that daily prices are well approximated by a random walk. Figure 1 shows these daily prices from July 18, 2010 to December 25, 2017 on a linear and a log scale. Both are informative.

A related question to efficiency is the volatility of prices. Much has been made of Bitcoin’s volatility. When prices change from \$.05 to \$16,000, volatility inevitably will be high. In fact, the variance of the log level is simply the squared difference between the log of the price at the end and the start of the period divided by the length of the period and variance inevitably partly reflects the increase in the level over the whole period or a sub-period.

A local level model (J. Durbin and S. J. Koopman, *Time Series Analysis by State Space Methods*) is one possible route to separating variance due to changes in the level of prices and variance due to trading and transitory information. We are pursuing this and a comparison with a Beveridge-Nelson decomposition.

Some emphasize the use of Bitcoin for illegal purchase of drugs and similar activities such as avoidance of capital controls. We have data on the physical locations of exchanges in most cases and will use this in conjunction with data on money laundering rules in different countries to see if there are any general effects of such rules on the exchanges.
